This paper was prepared for presentation at the SPE Deepwater Drilling and Completions Conference held in Galveston, Texas, USA, 10–11 September 2014.

This paper was selected for presentation by an SPE program committee following review of information contained in an abstract submitted by the author(s). Contents of the paper have not been reviewed by the Society of Petroleum Engineers and are subject to correction by the author(s). The material does not necessarily reflect any position of the Society of Petroleum Engineers, its officers, or members. Electronic reproduction, distribution, or storage of any part of this paper without the written consent of the Society of Petroleum Engineers is prohibited. Permission to reproduce in print is restricted to an abstract of not more than 300 words; illustrations may not be copied. The abstract must contain conspicuous acknowledgment of SPE copyright.

### **Abstract**

High strength-to-weight aluminum alloy drill pipe is a powerful torque and drag reduction tool for deviated wells. The aluminum alloy drill pipe enables to achieve strength to weight ratios equivalent to 160 ksi yield strength steels and is typical 30-50% lighter than similar steel drill pipe. An operator has recently tested aluminum alloy drill pipe in a complex and highly deviated well profile.

This paper presents the key findings regarding the benefits of drilling using aluminum drill pipes in a mixed aluminum-steel string compared to a string using steel pipes only. Firstly, the innovative drill pipe design is presented, followed by lessons learned during rig operations regarding pipe handling practices, rig compatibility and pipe inspection. Then, the paper presents results of an advanced torque, drag and buckling simulations taking into account the rigorous mechanical characteristics of aluminum drill pipe. In well planning phase, sensitivity analysis enabled to optimize the placement of aluminum drill pipe along the mixed aluminum-steel drill string according to the well profile and to predict anticipated torque, drag and loads on pipes while drilling. Through extensive modeling and field data interpretation, the paper presents a comparison of the overall drilling performances between steel only and aluminum-steel drill pipe string, and provides metrics in terms of torque and drag reduction. These results were then used to challenge horizontal and extended reach drilling well profiles where the utilization of steel drill pipes only has shown its limitation.

### **Introduction**

Many industrial and research studies<sup>1,2,3,4</sup> have exposed the idea of using non-steel drillstrings, such as aluminum alloys, in order to reduce torque and drag loads in long deviated and/or extended reach-drilling wells. Indeed, despite continuous improvement of steel materials to increase yield strength, aluminum drill pipe has been proposed as a viable alternative to drill these extreme long wells thanks mainly to its light weight characteristics. **Tab. 1** compares the mechanical properties of steel and aluminum grades, in terms of density, Young modulus, yield and tensile strength, and gives the strength-to-weight ratio for a 5 inch steel drill pipe (SDP) and a 5 7/8 aluminum drill pipe (ADP). This strength-to-weight ratio represents the ultimate length of a single size drillstring that can be suspended without exceeding the yield strength of the material. Aluminum drill pipes are characterized by higher strength-to-weight ratio than steel drill pipes due to a lighter specific weight despite reduced yield strength. This characteristic allows decreasing torque and drag loads while keeping a good resistance to axial, torsional and lateral loads. Lighter weight enables to reduce the contact side force between drill pipe and borehole, thus reducing friction between the drill string and the borehole. Less friction means not only that hook load and torque at surface are lower but also expected compression while running the drill string in the hole is less than the one generated along a drill string made exclusively of steel. However, aluminum alloys have more flexibility due to a reduced young modulus meaning that aluminum drill pipe buckles at a given compression lower than steel drill pipe. Nevertheless, depending of the well trajectory, coefficient of friction and application, the higher flexibility can be balanced by the reduced contact side forces
